Least-squares

Our objective is to find a model \mathbf{m} which is capable of reproducing our observable data \mathbf{d} . However, in practice, it is impossible to find a \mathbf{m} that solve exactly $\mathbf{g}(\mathbf{m})=\mathbf{d}$. As an alternative, one can minimize the **data residuals** (measure of the misfit) to some tolerance δ :

$$\mathbf{r}=\mathbf{d}-\mathbf{g}(\mathbf{m}) \quad (1)$$

We generally use the L_p norm to quantify the misfit:

$$\|\mathbf{r}\|_p = \left(\sum_{i=1}^m |r_i|^p \right)^{\frac{1}{p}} \leq \delta \quad (2)$$

SVD

Moore-Penrose inverse

If the problem is linear $g(\mathbf{m}) = \mathbf{G}\mathbf{m}$ then we can use the SVD

$$\mathbf{G} = [\mathbf{U}_p, \mathbf{U}_0] \begin{pmatrix} \mathbf{S}_p & 0 \\ 0 & 0 \end{pmatrix} [\mathbf{V}_p, \mathbf{V}_0]^T \quad (3)$$

where \mathbf{U} and \mathbf{V} are m by m and n by n orthogonal matrices, respectively, and \mathbf{S} is an m by n diagonal matrix with nonnegative diagonal elements called singular values arranged in decreasing size ($s_1 \geq s_2 \geq \dots \geq s_{\min(m,n)}$).

to compute a generalized inverse of the matrix \mathbf{G} , called the Moore-Penrose pseudoinverse:

$$\mathbf{G}^\dagger = \mathbf{V}_p \mathbf{S}_p^{-1} \mathbf{U}_p^T \quad (4)$$

Definition

We define the pseudoinverse solution m_\dagger to the inverse problem $\mathbf{G}\mathbf{m} = \mathbf{d}$:

$$m_\dagger = \mathbf{V}_p \mathbf{S}_p^{-1} \mathbf{U}_p^T \mathbf{d} = \sum_{i=1}^p \frac{\mathbf{U}_{:,i}^T (\mathbf{d} + \epsilon)}{s_i} \mathbf{V}_{:,i} \quad (5)$$

which **always** exist.

Least-squares

SVD

Gauss-Newton, Levenberg-Marquardt and Occam

Regularization freedom

Image appraisal

Time-lapse dedicated regularization

Resolution and covariance of the pseudoinverse solution

Definition

$$\text{Cov}(\mathbf{m}_{\dagger}) = \mathbf{G}^{\dagger} \text{Cov}(\mathbf{d}(\mathbf{G}^{\dagger})^T) \quad (6)$$

$$= \sigma^2 \sum_{i=1}^p \frac{V_{:,i} V_{:,i}^T}{s_i^2} \quad (7)$$

Note that as p increases, the variance increases.

Definition

The **model resolution matrix** \mathbf{R}_m is defined by:

$$\mathbf{m}_{\dagger} = \mathbf{G}^{\dagger} \mathbf{d} \simeq \mathbf{G}^{\dagger} \mathbf{G} \mathbf{m}_{true} \quad (8)$$

$$\mathbf{R}_m = \mathbf{G}^{\dagger} \mathbf{G} = \mathbf{V}_p \mathbf{V}_p^T \quad (9)$$

Tikhonov and the L-curve

We will examine another way of stabilizing the solution using the Tikhonov regularization, one of the most widely used technique to solve inverse problems (Tikhonov and Arsenin, 1977). It can be stated as follows:

$$\min ||\mathbf{m}||_2 \quad (10)$$

$$||\mathbf{Gm-d}||_2 \leq \delta \quad (11)$$

so that unneeded features will not appear in the regularized solution.

Draw Lcurve.

Note that this is equivalent to:

$$\min ||\mathbf{Gm-d}||_2 \quad (12)$$

$$||\mathbf{m}||_2 \leq \epsilon \quad (13)$$

the L-curve

Gauss-
Newton,
Levenberg-
Marquardt
and Occam

Regularization
freedom

Image
appraisal

Time-lapse
dedicated
regularization

Applying the method of the Lagrange multiplier we have:

$$\min ||\mathbf{Gm-d}||_2 + \alpha^2 ||\mathbf{m}||_2 \quad (14)$$

where α is a **regularization parameter**. By computing the derivative of this functional with respect to \mathbf{m} and using the SVD of \mathbf{G} we can find the solution \mathbf{m}_α

$$\mathbf{m}_\alpha = \sum_{i=1}^k \frac{s_i^2}{(s_i^2 + \alpha^2)} \frac{\mathbf{U}_{:,i}^T \mathbf{d}}{s_i} \mathbf{V}_{:,i} \quad (15)$$

The quantities $\frac{s_i^2}{(s_i^2 + \alpha^2)}$ are called filter factors. They control the instabilities induced by the small s_i

Higher-order Tikhonov regularization

The Tikhonov term $||\mathbf{m}||_2$ can be written as $||\mathbf{Lm}||_2$ where $\mathbf{L} = \mathbf{I}$ or the zeroth order derivative operator. Instead of using the zeroth order regularization we can choose to use the first, second, third...derivative:

$$\mathbf{L}_1 = \begin{bmatrix} -1 & 1 & & \\ & -1 & 1 & \\ & & -1 & 1 \\ & & & 1 \end{bmatrix} \quad (16)$$

and the inverse problem becomes:

$$\min ||\mathbf{Gm-d}||_2 + \alpha^2 ||\mathbf{L}_p \mathbf{m}||_2 \quad (17)$$

and can be solved using the generalized singular value decomposition (\mathbf{G}, \mathbf{L}).

Consider problems of the form $\mathbf{d} = g(\mathbf{m})$ where \mathbf{m} is a n by 1 model parameter vector and \mathbf{d} is a m by 1 data vector. As for the linear problem, we want to find the minimum of:

$$f(\mathbf{m}) = \sum_i^m \underbrace{\left(\frac{g(\mathbf{m})_i - d_i}{\sigma_i} \right)^2}_{f_i(\mathbf{m})} \quad (18)$$

$$f(\mathbf{m}) = \sum_i^m f_i(\mathbf{m})^2 \quad (19)$$

To compute the increment on the model we had to solve:

$$\nabla f(\mathbf{m}^0) = -\frac{1}{2}\nabla^2 f(\mathbf{m}^0)\Delta\mathbf{m} \quad (20)$$

which becomes (re-introducing the iteration index k)

$$\mathbf{J}(\mathbf{m}^k)^T \mathbf{J}(\mathbf{m}^k) \Delta\mathbf{m}^k = -\mathbf{J}(\mathbf{m}^k)^T \mathbf{f}(\mathbf{m}^k) \quad (21)$$

Where the $\mathbf{J}^T \mathbf{J}$ term approximates the Hessian $\nabla^2 f(\mathbf{m}^0)$. Note the similarity between this equation and the normal equations from the linear problem case:

$$\mathbf{G}^T \mathbf{G} \mathbf{m} = \mathbf{G}^T \mathbf{d} \quad (22)$$

The cost is mainly associated with the computation of the Jacobian:

- Analytical expression.
- Finite-differences.
- Adjoint state methods
(Plessix, 2006).
- Mesh adaptation. (Rucker et al., 2006)
- Approximation or compression of \mathbf{J} (Broyden, 1965; Li et al., 2003)
- GPU computation (Borsic et al., 2012)

This method will fail if the product $\mathbf{J}(\mathbf{m}^k)^T \mathbf{J}(\mathbf{m}^k)$ is close to singularity. To ensure convergence, one can add a positive term on the diagonal of this product resulting in the **Levenberg-Marquardt** method:

$$(\mathbf{J}(\mathbf{m}^k)^T \mathbf{J}(\mathbf{m}^k) + \lambda \mathbf{I}) \Delta \mathbf{m}^k = -\mathbf{J}(\mathbf{m}^k)^T \mathbf{f}(\mathbf{m}^k) \quad (23)$$

where λ must be adjusted in order to ensure convergence. Note the similarity with the Tikhonov regularized problem:

$$(\mathbf{G}^T \mathbf{G} + \alpha^2 \mathbf{I}) \mathbf{m} = \mathbf{G}^T \mathbf{d} \quad (24)$$

regularization

- 1 Choose \mathbf{m}^0
- 2 Pick a λ value as small as possible that minimizes the misfit (downhill steps)
- 3 solve for $\Delta \mathbf{m}^k$
- 4 Let $\mathbf{m}^{k+1} = \mathbf{m} + \Delta \mathbf{m}^k$
- 5 Let $k = k + 1$
- 6 Check convergence criteria

Step 6 of the algorithm correspond to the establishment of the convergence of the solution. We can consider the three following stopping criteria:

- $\nabla f(\mathbf{m}^k) \approx 0$
- The successive models \mathbf{m}^k do not evolve
- The residuals $f(\mathbf{m})$ do not change
- Am I trapped in a local minima ? (yes...) → hybrid methods combined with LM (accepts uphill steps)

Mule et al., 2016

Occam principle

In science, Occam razor is used as a heuristic (rule of thumb) to guide scientists in the development of theoretical models rather than as an arbiter between published models, in our case, it was translated as: "**In doubt, smooth**" or more formally

$$\min ||\mathbf{Lm}||_2 \quad (25)$$

$$||\mathbf{g}(\mathbf{m}) - \mathbf{d}||_2 \leq \delta \quad (26)$$

or

$$\min ||\mathbf{g}(\mathbf{m}) - \mathbf{d}||_2^2 + \lambda ||\mathbf{Lm}||_2^2 \quad (27)$$

Letting

$$\hat{\mathbf{d}}(\mathbf{m}^k) = \mathbf{d} - \mathbf{g}(\mathbf{m}^k) + \mathbf{J}(\mathbf{m}^k)\mathbf{m}^k \quad (28)$$

The Gauss-Newton update becomes:

$$\mathbf{m}^k + \Delta\mathbf{m}^k = (\mathbf{J}(\mathbf{m}^k)^T \mathbf{J}(\mathbf{m}^k) + \lambda^2 \mathbf{L}^T \mathbf{L})^{-1} \mathbf{J}(\mathbf{m}^k)^T \hat{\mathbf{d}}(\mathbf{m}^k) \quad (29)$$

And the geophysicist replied: Which model do you want?

(Constable et al., 2015)

Consider that we have access to borehole geological log \rightarrow boundaries

Kaipio et al., 1999)

$$\|W_d(\mathbf{d} - f(\mathbf{m}))\|^2 + \lambda(\|W_m(\mathbf{m} - \mathbf{m}_0)\|^2 + \alpha\|\mathbf{m} - \mathbf{m}_0\|^2)$$

with

$$W_m^T W_m = \beta_t W_t^T W_t + \beta_n W_n^T W_n$$

We could also have a borehole geophysical log \rightarrow variogram and reference values

$$\|W_d(\mathbf{d} - f(\mathbf{m}))\|^2 + \lambda \|C_m^{-0.5}(\mathbf{m} - \mathbf{m}_0)\|^2$$

with C_m the covariance matrix obtained from a vertical variogram but assuming some horizontal range.

DOI index

To appraise the obtained image, it is often useful to use the DOI Index (depth of investigation, Oldenburg and Li, 1999):

$$\frac{|\mathbf{m}^1 - \mathbf{m}^2|}{|\mathbf{m}_{ref1} - \mathbf{m}_{ref2}|}$$

Resolution and sensitivity

There are several commonly used appraisal tools that one can use to judge the quality of an inverse model (in addition to misfit criteria). One of the difficulty associated with them is to define a threshold.

Consider the following regularization functional (minimum gradient support, Portniaguine and Zhdanov, 1999):

$$\int_V \frac{(\nabla m) \cdot \nabla m}{(\nabla m) \cdot \nabla m + \beta^2} dV$$

The choice of the β parameter controls the stability of the gradient \rightarrow here we propose to select based on a line search on the time-lapse residuals (no other prior information required).
