Abstract

As a model for elliptic boundary value problems, we consider the Dirichlet problem for an elliptic operator. Solutions have singular expansions near the conical points of the domain. We give formulas for the coefficients in these expansions.

1. INTRODUCTION

We consider bounded $n$-dimensional domains with conical points, as Kondrat’ev in [4]. For simplicity, we suppose that there is only one conical point and that it is located in 0. We denote $\Omega$ our domain and we assume that its boundary is $C^\infty$ outside 0 and that it coincides with a cone $\Gamma$ in a neighborhood of 0. We denote $x$ the cartesian coordinates in $\mathbb{R}^n$ and $(r, \theta)$ the spherical coordinates. The spherical section of $\Gamma$ is denoted $G$:

$$\Gamma \cap S^{n-1} = G.$$

We are interested in the Dirichlet boundary value problem for an elliptic operator $P(x; D_x)$ of order $2m$. We assume that the coefficients of this operator are $C^\infty(\overline{\Omega}\setminus 0)$. We have to sharpen this assumption. We will consider three cases ($\mathcal{C}_1$), ($\mathcal{C}_2$) and ($\mathcal{C}_3$), each of them being more general than the previous one:

- ($\mathcal{C}_1$): $P$ is homogeneous with constant coefficients; then, there exists an operator $\mathcal{L}$ with $C^\infty(\overline{G})$ coefficients such that

$$P(D_x) = r^{-2m} \mathcal{L}(\theta; r \partial_r, \partial_\theta).$$
• \((C2)\) : \(P\) has \(C^\infty(\overline{\Omega})\) coefficients; then, if \(L\) denotes the principal part of \(P(0; D_x)\), then \(L\) satisfies the assumption of \((C1)\) and the difference:

\[
R(x; D_x) \equiv P(x; D_x) - L(D_x)
\]

is a remainder.

• \((C3)\) : there exists an operator \(L\) with \(C^\infty(G)\) coefficients such that the difference:

\[
R(x; D_x) \equiv P(x; D_x) - r^{-2m} L(\theta; r \partial_r, \partial_\theta)
\]

is a remainder in a sense we are going to explain.

The Coulomb operator \(-\Delta + \frac{1}{r}\) satisfies the assumptions of \((C3)\). To explain what we mean by remainder, we need some weighted Sobolev spaces.

As usual, \(H^m(\Omega)\) denotes the closure of \(D(\Omega)\) in \(H^m(\Omega)\) and \(H^{-m}(\Omega)\) is its dual space. For any positive integer \(k\) and any real \(\beta\), \(H^k_\beta(\Omega)\) is defined as:

\[
H^k_\beta(\Omega) = \{ u \in D'(\Omega) \mid r^{-k+|\alpha|} D^\alpha_x u \in L^2(\Omega) \forall \alpha, |\alpha| \leq k \}.
\]

We also define \(H^s_\beta(\Omega)\) for any positive real \(s\) in a natural way – cf for instance the appendix A in [1] –, and for any negative \(s\) by duality.

For any \(s > 0\) and any \(\beta\), the operators \(P\) and \(L\) in case \((C2)\), and \(r^{-2m} L\) in cases \((C1)\) and \((C3)\) are continuous:

\[
H^{s+m}_\beta(\Omega) \to H^{s-m}_\beta(\Omega).
\]

Moreover, in case \((C2)\), the remainder \(R\) is continuous:

\[
H^{s+m}_\beta(\Omega) \to H^{s-m}_{\beta-1}(\Omega).
\]

Now, the assumption in the case \((C3)\) is that there exists \(\delta \in ]0, 1]\) such that for any \(s \geq 0\) and \(\beta\) the remainder \(R\) is continuous:

\[
H^{s+m}_\beta(\Omega) \to H^{s-m}_{\beta-\delta}(\Omega). \tag{1.1}
\]

If \(a_\alpha\) denote the coefficients of \(R\):

\[
R(x; D_x) = \sum_{|\alpha| \leq 2m} a_\alpha D^\alpha_x,
\]

the assumption \((1.1)\) holds if:

\[
\forall \gamma \in \mathbb{N}^n, \quad D^\gamma_x a_\alpha \text{ is a } O(r^{|\alpha| - 2m - \delta - |\gamma|}).
\]
With the above assumptions, we are interested in the structure of any solution $u$ of the following Dirichlet problem:

$$u \in \dot{H}^m(\Omega), \quad Pu \in H_{\beta}^{s-m}(\Omega), \quad \text{with} \quad s > 0 \quad \text{and} \quad s - \beta > 0. \quad (1.2)$$

Since $s > 0$ and $s - \beta > 0$, $H_{\beta}^{s-m}(\Omega)$ is (compactly) embedded in $H^{-m}(\Omega)$. So $Pu$ has in a sense more regularity than $u$. Of course, it is possible to consider more general situations than (1.2) i.e. to assume that $u$ belongs to some weighted space. The solution of this problem would be essentially the same as (1.2). We chose (1.2), because it is the natural framework when $P$ is strongly elliptic.

The assumptions of case (C2) are these of Kondrat’ev in [4]. We also took these assumptions in our earlier works [2] and [3]. The assumptions of case (C3) were introduced by Maz’ja and Plamenevskii in [7]. Kondrat’ev proved the existence of an expansion of the solutions of (1.2) in the form of a sum $\sum_i c_i S_i$ where the $S_i$ only depend on $\Omega$ and $P$ and the $c_i$ are some coefficients. Maz’ja and Plamenevskii in [6] and in [7] gave formulas for these coefficients; we also studied these coefficients in [2] and [3] in a different framework. What we give here extends in a certain sense [7] and [2].

To end this section, let us state a Fredholm theorem. Such a result is related to asymptotics of solutions: a solution of (1.2) can be split into a singular part (asymptotics) and a regular part (remainder) when the assumptions of the following theorem hold.

We need some notations. We denote $P_{\beta}^s$ the following operator:

$$P_{\beta}^s : \dot{H}^m_{\beta-s}(\Omega) \cap H^{s+m}_{\beta}(\Omega) \to H_{\beta}^{s-m}(\Omega) \quad \text{where} \quad \dot{H}^m(\Omega) \quad \text{is the closure of} \quad \mathcal{D}(\Omega) \quad \text{in} \quad H^{m}_{\gamma}(\Omega).$$

We will simply denote $P_{\beta}$ the operator $P_{\beta}^0$.

$P^*_{-\beta}$ denotes the adjoint of $P_{\beta}$. It acts

$$P^*_{-\beta} : \dot{H}^m_{-\beta}(\Omega) \to H^{-m}_{-\beta}(\Omega).$$

For any $\lambda \in \mathbb{C}$, $\mathcal{L}(\lambda)$ is the operator:

$$\mathcal{L}(\theta; \lambda, \partial_\theta) : \dot{H}^m(G) \to H^{-m}(G).$$

$\mathcal{L}(\lambda)$ is one to one except when $\lambda$ belongs to a countable set in $\mathbb{C}$, which can be called the spectrum of $\mathcal{L}$ and is denoted by $Sp(\mathcal{L})$.

**Theorem 1.1** In the case (C3), we assume that $s \geq 0$, $\beta \in \mathbb{R}$, $s - \beta \geq 0$ and that

$$\forall \lambda \quad \text{such that} \quad \text{Re} \lambda = s + m - \beta - \frac{n}{2}, \quad \lambda \not\in Sp(\mathcal{L}).$$

Then $P_{\beta}^s$ is a Fredholm operator.
2. THE MODEL PROBLEM

In this section, we will only study the case \((C1)\), when the operator is homogeneous with constant coefficients. We recall that \(P = L\).

For each \(\lambda \in \mathcal{S}p(L)\), the following space:

\[
Z^\lambda := \{ u \mid u = r^\lambda \sum_q \log^q r u_q(\theta), \ u_q \in \dot{H}^m(G), \ Lu = 0 \}
\]

is not reduced to 0: all function of the form \(r^\lambda u_0\) where \(u_0\) belongs to \(\text{Ker} \ L(\lambda)\), is an element of \(Z^\lambda\). Let \(\sigma^\lambda_{\nu}\), for \(\nu = 1, \ldots, N^\lambda\) denote a basis of this space.

**Theorem 2.1** In the case \((C1)\), we assume the same hypotheses about \(s\) and \(\beta\) as in Theorem 1.1. Let \(\eta\) be a cut-off function which is equal to 1 in a neighborhood of 0 and has its support in another neighborhood of 0 where \(\Omega\) coincides with the cone \(\Gamma\). We assume that \(u \in \dot{H}^m(\Omega)\) is such that \(P u \in H^{s-m}(\Omega)\). Then there exist coefficients \(c^\lambda_{\nu}\) such that

\[
u - \sum_{\lambda \in \mathcal{S}p(L)} \sum_{\mu, \mu' \in \mathcal{S}p(L)} \sum_{\nu, \nu' = 1}^{N^\lambda} c^\lambda_{\nu} \eta \sigma^\lambda_{\nu} \in H^{s+m}(\Omega).
\]

If \(\text{Ker} \ P_0\) is contained in \(H^{s+m}(\Omega)\), then the coefficients \(c^\lambda_{\nu}\) only depend on \(P u\). This is the reason for the introduction of the following assumption.

If \(u \in \dot{H}^m(\Omega)\) is such that \(Pu = 0\) then \(u \in H^{m-s}(\Omega)\). \(2.1\)

If (2.1) holds, as a consequence of a well-known regularity result for corner problems, such an element of the kernel belongs to any space \(H^{m+t}_{\beta-s+t}(\Omega)\) for any \(t \geq 0\) (see Theorem 2.9 of [2] for instance).

Now, we are going to construct dual singular functions. We start with a result from [6].

**Lemma 2.2** For all \(\lambda \in \mathcal{S}p(L)\), there exists a basis \(\tau^\lambda_{\nu}\), for \(\nu = 1, \ldots, N^\lambda\) of the space

\[
\check{Z}^\lambda := \{ u \mid u = r^{2m-n} \sum_q \log^q r v_q(\theta), \ v_q \in \dot{H}^m(G), \ L^* u = 0 \}
\]

such that \(\forall \mu, \mu' \in \mathcal{S}p(L), \forall \nu, \nu' \)

\[
\int_{\Omega} L(\eta \sigma^\mu_{\nu}) \overline{\tau^\mu_{\nu'}} = \delta_{\mu \mu'} \delta_{\nu \nu'}.
\]

We set $T^\lambda = \eta \tau^\lambda$. We have

\[ \forall \lambda, \, m - \frac{n}{2} < \text{Re} \lambda < s - \beta + m - \frac{n}{2}, \quad T^\lambda \not\in H_0^m(\Omega) \text{ and } T^\lambda \not\in \tilde{H}_m^{s-\beta}(\Omega). \]

Due to assumption 2.1, there exists $Y^\lambda \in \tilde{H}^m(\Omega)$ such that $P^* Y^\lambda = P^* T^\lambda$. We set

\[ K^\lambda = T^\lambda - Y^\lambda. \]

**Theorem 2.3** In the case ($C1$) and with the hypothesis (2.1), we assume the same hypotheses about $s$ and $\beta$ as in Theorem 1.1 and Theorem 2.1. Then

\[ c^\lambda = \int_\Omega P u K^\lambda dx. \]

When $P = \Delta$ and when $\Gamma$ is a plane sector with opening $\omega$, the $\sigma^\lambda$ are the functions $r^{\frac{k\pi}{\omega}} \sin \frac{k\pi \theta}{\omega}$ for $k \in \mathbb{N}^*$ and the $\tau^\lambda$ are the functions $-\frac{1}{k\pi} r^{\frac{k\pi}{\omega}} \sin \frac{k\pi \theta}{\omega}$.

### 3. THE GENERAL PROBLEM

Now, we will work in the framework of the general case ($C3$). All the above results can be extended in a certain sense to the case ($C3$). We are going to introduce auxiliary functions. In the case ($C2$), the structure of these functions is more precisely known.

First, we construct elements of the kernel of $P^*$ in the same way by subtracting a corrective function $Y^\lambda$ from $T^\lambda$. The difference lies in the construction of $Y^\lambda$. They cannot be found in $\tilde{H}^m(\Omega)$ in general but in a larger space.

**Proposition 3.1** In the case ($C3$) and with the hypothesis (2.1), let $\lambda \in \mathcal{S}(\mathcal{L})$ such that $m - \frac{n}{2} < \text{Re} \lambda$. We set

\[ \gamma(\lambda) := \text{Re} \lambda - m + \frac{n}{2}. \]

Then $\forall \varepsilon > 0$, we have

\[ T^\lambda \in H_{\gamma(\lambda) + \varepsilon}^m(\Omega) \quad \text{and} \quad T^\lambda \not\in H_{\gamma(\lambda)}^m(\Omega). \]  

(3.1)

Let $\delta' = \min\{\delta, \gamma(\lambda)\}$, where $\delta$ was introduced in (1.1). Then there exists $Y^\lambda$ which satisfies the homogeneous Dirichlet conditions and such that

\[ P^* T^\lambda = P^* Y^\lambda \quad \text{and} \quad \forall \varepsilon > 0, \, Y^\lambda \in H_{\gamma(\lambda) - \delta' + \varepsilon}^m(\Omega). \]

We introduce :

\[ K^\lambda = T^\lambda - Y^\lambda. \]
The $K^\lambda_\nu$ for $\lambda \in \text{Sp}(L)$, $m - \frac{n}{2} < \text{Re} \lambda < s - \beta + m - \frac{n}{2}$ and for $\nu = 1, \ldots, N^\lambda$ form a basis of

$$\text{Ker } P^*_ {s-\beta} / \text{Ker } P^*_0.$$ 

Remark 3.2 In the case (C2), the $Y^\lambda_\nu$ can be constructed as a sum of terms

$$T^\lambda_{\nu,j} = \eta r^{-\lambda+2n-\nu+j} \sum \log^q r \nu^\lambda_{\nu,j,q}(\theta)$$

with $1 \leq j \leq \text{Re} \lambda - m + \frac{n}{2}$ and of an element $X^\lambda_\nu \in \tilde{H}^m(\Omega)$.

In the case (C1), the functions $T^\lambda_{\nu,j}$ are equal to zero and $Y^\lambda_\nu = X^\lambda_\nu$ (see §4 of [2]).

Proof. First step. Let us prove the existence of $Y^\lambda_\nu$. By construction, $L^* T^\lambda_{\nu,j} = 0$ in a neighborhood of 0 ; as a consequence of the assumption (1.1), $P^* T^\lambda_{\nu,j} \in H^{-m}_{\lambda+\gamma+\epsilon-\delta'}(\Omega)$. We want to prove that

$$P^* T^\lambda_{\nu,j} \in \text{Rg } P^*_{\gamma+\epsilon-\delta'}.$$  \hspace{1cm} (3.2)

But, the regularity of $T^\lambda_{\nu,j}$ yields $P^* T^\lambda_{\nu,j} \in \text{Rg } P^*_{\gamma+\epsilon}$.

We chose $\epsilon$ small enough such that the ranges of $P^*_{\gamma+\epsilon}$ and of $P^*_{\gamma+\epsilon-\delta'}$ are closed. We have

$$\text{Rg } P^*_{\gamma+\epsilon} = (\text{Ker } P_{\gamma+\epsilon})^\perp \quad \text{and} \quad \text{Rg } P^*_{\gamma+\epsilon-\delta'} = (\text{Ker } P_{\gamma+\epsilon-\delta'})^\perp.$$

The hypothesis (2.1) yields that

$$\text{Ker } P_{\gamma+\epsilon} = \text{Ker } P_{\gamma+\epsilon-\delta'}.$$

So, we have obtained (3.2).

Second step. Let us prove that the $K^\lambda_\nu$ are independent from each other modulo $\text{o } H^m(\Omega)$. Let us suppose that they are not independent and that there exist non zero coefficients $c^\lambda_\nu$ such that $\sum c^\lambda_\nu K^\lambda_\nu \in \tilde{H}^m(\Omega)$. Let $\xi$ be the largest real part of the $\lambda$ which are associated with a non zero coefficient. Since the whole sum belongs to $\tilde{H}^m(\Omega)$, we deduce by construction of the $K^\lambda_\nu$ that

$$\exists \rho > 0, \quad \sum_{\text{Re}\lambda = \xi} c^\lambda_\nu T^\lambda_\nu \in H^m_{\xi-m+n-\rho}(\Omega).$$

The form of the $T^\lambda_\nu$ (cf (3.1)) allows to show that the coefficients in the above sum are all zero. We have obtained a contradiction.

Third step. Let $\gamma$ be $s - \beta$ and let $n_\gamma$ be the cardinal of the set

$$\{K^\lambda_\nu \mid m - \frac{n}{2} < \text{Re} \lambda < s - \beta + m - \frac{n}{2} \quad \text{and} \quad \nu = 1, \ldots, N^\lambda\}.$$

We have to show that the dimension of $\text{Ker } P^*_\gamma$ is equal to the dimension of $\text{Ker } P^*_0$ plus $n_\gamma$. We rely on an index calculus. Let us choose $\gamma_0, \ldots, \gamma_J$ such
that
\[
\begin{aligned}
0 \leq & \gamma_0 \leq \ldots \leq \gamma_J = \gamma \\
\forall j = 1, \ldots, J : & \gamma_j - \gamma_{j-1} \leq \delta \\
\text{Sp}(\mathcal{L}) \cap \{ \lambda \in \mathbb{C} \mid m - \frac{n}{2} < \text{Re} \lambda < m - \frac{n}{2} + \gamma_0 \} = \emptyset \\
\forall j = 1, \ldots, J : & \text{Sp}(\mathcal{L}) \cap \{ \lambda \in \mathbb{C} \mid \text{Re} \lambda = m - \frac{n}{2} + \gamma_j \} = \emptyset.
\end{aligned}
\]
(3.3)

For each \( j = 1, \ldots, J \), the functions \( u \in \mathcal{H}_{m-\gamma_j}(\Omega) \) such that \( Lu \in \mathcal{H}_{-m}(\Omega) \) can be written as a sum of a regular part in \( \mathcal{H}_{m-\gamma_j}(\Omega) \) and a singular part which is a combination of the \( \eta \sigma^\lambda \) with \( \lambda \in \text{Sp}(\mathcal{L}) \) and \( m - \frac{n}{2} + \gamma_{j-1} < \text{Re} \lambda < m - \frac{n}{2} + \gamma_j \). Due to (1.1), the same holds for the operator \( P \). Applying the result of the appendix B of [1] for each pair \( (P_{-\gamma_j-1}, P_{-\gamma_j}) \) and summing over \( j = 1, \ldots, J \), we get
\[
\text{Ind} P_{-\gamma_0} - \text{Ind} P_{-\gamma} = n_{\gamma}.
\]
As a consequence of the assumption (2.1), \( \text{Ker} P_{-\gamma_0} = \text{Ker} P_{-\gamma} \). Then
\[
\text{Codim Rg} P_{-\gamma} - \text{Codim Rg} P_{-\gamma_0} = n_{\gamma}.
\]
So for the adjoints, we get
\[
\dim \text{Ker} P^*_{\gamma_0} - \dim \text{Ker} P^*_{\gamma} = n_{\gamma}.
\]
We end the proof by noting that the construction of \( \gamma_0 \) infers \( \text{Ker} P^*_{\gamma_0} = \text{Ker} P^*_0 \).

We are going to construct the singularities now, i.e. a basis of functions belonging to \( \mathcal{H}^m(\Omega) \), which are not in \( H^{s+m}_{\beta}(\Omega) \) and such that \( Pu \in H^{s-m}_{\beta}(\Omega) \). In the case (C1), such a basis is formed by the \( \eta \sigma^\lambda \) (cf Theorem 2.1). Such a result extends to the case (C3) only if \( s - \beta \leq \delta \). Let us state that with \( s = 0 \):

**Lemma 3.3** In the case (C3), let \( \tau \) and \( \tau' \) such that \( 0 < \tau' - \tau \leq \delta \). We assume that
\[
\text{Sp}(\mathcal{L}) \cap \{ \lambda \in \mathbb{C} \mid \text{Re} \lambda = m - \frac{n}{2} + \tau \} = \emptyset.
\]
and that \( u \in \mathcal{H}^m_{\tau'}(\Omega) \) is such that \( Pu \in \mathcal{H}^{-m}_{\tau}(\Omega) \). Then there exist coefficients \( c^\lambda \) such that
\[
\begin{aligned}
u \in \mathcal{L}:
\sum_{\nu \in \mathcal{L}}^N & c^\lambda \eta \sigma^\lambda \in H^m_{\tau}(\Omega).
\end{aligned}
\]
As we already explained in the above proof, this is a simple consequence of the assumptions of (1.1) and of the corresponding result for \( L \) which is known [4].

In the case (C2), when \( s - \beta > 1 \), \( P(\eta \sigma^\lambda) \) does not belong to \( H^{s-m}_{\beta}(\Omega) \) in general but there exist
\[
\sigma^\lambda_{\nu,j} = r^{\lambda+j} \sum \log r \ u^\lambda_{\nu,j}(\theta)
\]
where $u_{\nu,j,q}^\lambda \in \tilde{H}^m(G)$ and such that

$$P[\eta (\sigma_{\nu}^\lambda + \sum_{1 \leq j \leq s-\beta+m-\frac{n}{2}} \sigma_{\nu,j}^\lambda)] \in H_{\beta}^{s-m}(\Omega)$$

see §4.B of [2].

In the general case (C3), we have another construction, which is less explicit, as in the previous proposition 3.1.

**Proposition 3.4** In the case (C3) and with the hypothesis (2.1), let $\lambda \in Sp(\mathcal{L})$ such that $m - \frac{n}{2} < \text{Re} \lambda$. With the notation of Proposition 3.1 for all $\varepsilon > 0$, we have

$$\eta \sigma_{\nu}^\lambda \in H_{-\gamma(\lambda)+\varepsilon}^m(\Omega) \quad \text{and} \quad \eta \sigma_{\nu}^\lambda \notin H_{-\gamma(\lambda)}^m(\Omega). \quad (3.4)$$

Then there exists $Z_{\nu}^\lambda$ which satisfies the homogeneous Dirichlet conditions and such that

$$P(\eta \sigma_{\nu}^\lambda - Z_{\nu}^\lambda) \in C^\infty_0(\overline{\Omega} \setminus 0) \quad \text{and} \quad \forall \varepsilon > 0, \ Z_{\nu}^\lambda \in H_{-\gamma(\lambda)-\delta+\varepsilon}^m(\Omega).$$

We introduce:

$$S_{\nu}^\lambda = \eta \sigma_{\nu}^\lambda - Z_{\nu}^\lambda \quad \text{and} \quad F_{\nu}^\lambda := PS_{\nu}^\lambda.$$  

The $F_{\nu}^\lambda$ for $\lambda, \nu$ satisfying

$$\lambda \in Sp(\mathcal{L}), \ m - \frac{n}{2} < \text{Re} \lambda < s - \beta + m - \frac{n}{2} \quad \text{and} \quad \nu = 1, \ldots, N^\lambda \quad (3.5)$$

form a basis of

$$(H_{\beta}^{s-m}(\Omega) \cap \text{Rg} P_0) / \text{Rg} P_{\beta}^s.$$  

**Proof.** First step. As a consequence of Proposition 3.1, for any $u \in \tilde{H}^m(\Omega)$ such that $Pu \in H_{\beta-s}^m(\Omega)$, the following equivalence holds

$$u \in H_{\beta-s}^m(\Omega) \iff \forall \lambda, \nu \quad \text{as in (3.5)} \quad P_u, K_{\nu}^\lambda = 0.$$  

Due to a classical regularity result for corner problems (see for instance the statement given in [2] p.33), if $u \in \tilde{H}_{\beta-s}^m(\Omega)$ satisfies $Pu \in H_{\beta-s}^{s-m}(\Omega)$, then $u \in H_{\beta}^{s+m}(\Omega)$. Thus we have only to consider the above equivalence.

Since the $K_{\nu}^\lambda$ are functions as well as all elements of the kernel of any operator $P_\tau^*$, there exist $\tilde{F}_{\nu}^\lambda \in C^\infty_0(\overline{\Omega} \setminus 0) \cap \text{Rg} P_0$ such that

$$\forall \lambda, \nu \quad \text{and} \quad \lambda', \nu' \quad \text{as in (3.5)} : \quad <\tilde{F}_{\nu}^\lambda, K_{\nu'}^{\lambda'} > = \delta_{\lambda,\lambda'} \delta_{\nu,\nu'}.$$  

Let $\tilde{S}_{\nu}^\lambda \in \tilde{H}^m(\Omega)$ be such that $PS_{\nu}^\lambda = \tilde{F}_{\nu}^\lambda$. We have now to construct the $S_{\nu}^\lambda$ satisfying the assertions of Proposition 3.4 as linear combinations of the $\tilde{S}_{\nu}^\lambda$.  

8
Second step. We use again the \( \gamma_j \) satisfying (3.3) we have introduced in the previous proof. Applying Lemma 3.3 for \( \tau = -\gamma_1 \) and \( \tau' = -\gamma_0 \), we obtain that the \( \tilde{S}_\nu^\lambda \) for \( m - \frac{n}{2} + \gamma_0 < \Re \lambda < m - \frac{n}{2} + \gamma_1 \), generate

\[
\{ \eta \sigma_\nu^\lambda \mid m - \frac{n}{2} + \gamma_0 < \Re \lambda < m - \frac{n}{2} + \gamma_1 \}
\]

modulo \( \hat{H}_{m-\gamma_1} \). Thus, for any such \( \lambda \), there exist \( Z_\nu^\lambda \in \hat{H}_{m-\gamma_1} \) such that \( \eta \sigma_\nu^\lambda - Z_\nu^\lambda \) is a linear combination of the \( \tilde{S}_\nu^\lambda \). So, the functions \( S_\nu^\lambda \) are constructed for \( m - \frac{n}{2} + \gamma_0 < \Re \lambda < m - \frac{n}{2} + \gamma_1 \).

For the next step, corresponding to the weights \( -\gamma_1 \) and \( -\gamma_2 \), we use the same arguments where we replace the \( \tilde{S}_\nu^\lambda \) for \( m - \frac{n}{2} + \gamma_1 < \Re \lambda < m - \frac{n}{2} + \gamma_2 \) by the functions

\[
\tilde{S}_\nu^\lambda - \sum_{m - \frac{n}{2} + \gamma_0 < \Re \lambda' < m - \frac{n}{2} + \gamma_1} \frac{d_\nu^\lambda}{S_\nu^\lambda'}
\]

where, according to Lemma 3.3, the coefficients \( d_\nu^\lambda \) are chosen such that all the above functions belong to \( H_{m-\gamma_1} \).

Step by step, we reach \( \gamma_J = \gamma \) and our \( S_\nu^\lambda \) are independent and their number is \( n_\gamma \), what we need.

Now it is not too difficult to deduce from the two previous propositions and from the Green formula the three following statements.

With the functions \( S_\nu^\lambda \) we have just constructed, we have the extension of Theorem 2.1 to the case \( (C3) \).

**Theorem 3.5** In the case \( (C3) \) and with the hypothesis (2.1), we assume the same hypotheses about \( s \) and \( \beta \) as in Theorem 1.1 and Theorem 2.1. We assume that \( u \in \hat{H}^m(\Omega) \) is such that \( Pu \in H_\beta^{-m}(\Omega) \). Then there exist coefficients \( c_\nu^\lambda \) such that

\[
u \in S \}\}

As a result of the previous constructions, we have some independent functions \( \tilde{S}_\nu^\lambda \) such that

\[
< PS_\nu^\lambda, K_\nu'^\lambda > = \delta_{\lambda,\lambda'} \delta_{\nu,\nu'}.
\]

and the singularities \( S_\nu^\lambda \) are a basis of the space generated by the \( \tilde{S}_\nu^\lambda \). Thus, we can show

**Lemma 3.6** Under the assumptions of Theorem 3.5, there exists a basis \( \tilde{K}_\nu^\lambda \) of the space generated by the \( K_\nu^\lambda \) for \( m - \frac{n}{2} < \Re \lambda < s - \beta + m - \frac{n}{2} \), such that

\[
< PS_\nu^\lambda, \tilde{K}_\nu'^\lambda > = \delta_{\lambda,\lambda'} \delta_{\nu,\nu'}.
\]
The $\tilde{K}_\nu^\lambda$ have the form

$$\tilde{K}_\nu^\lambda = \sum_{\text{Re} \, \lambda' \geq \text{Re} \, \lambda} d_{\nu'}^\lambda K_{\nu'}^\lambda.$$ 

With these new elements of the kernel of $P^*$ we have

**Theorem 3.7** Under the assumptions of Theorem 3.5

$$c_{\nu}^\lambda = \int_{\Omega} P u \, \overline{K}_\nu^\lambda \, dx.$$ 

The above results have to be compared with the following statements of [7]: corollaries 3.1 and 3.2, theorems 3.3 and 3.4. Our hypothesis (2.1) is more general than the hypothesis of [7], which in our framework would correspond to

$$P \text{ is one to one } : \tilde{H}^m(\Omega) \to H^{-m}(\Omega).$$

The paper [5] gives similar expressions for the coefficients of the singularities in a different framework.

In the case (C2), under the following extra assumption

$$\{ \forall \lambda, \lambda' \in \mathcal{S}p(\mathcal{L}) \text{ such that } \text{Re} \lambda, \text{Re} \lambda' \in ]m - \frac{n}{2}, s - \beta + m - \frac{n}{2}[: \lambda - \lambda' \not\in \mathbb{N} \setminus 0 \} \quad (3.6)$$

the $\tilde{K}_\nu^\lambda$ and the $K_{\nu}^\lambda$ coincide with each other and the formula for the coefficients is the same as in Theorem 2.3:

$$c_{\nu}^\lambda = \int_{\Omega} P u \, \overline{K}_\nu^\lambda \, dx.$$ 

In the case (C2), it is natural to consider $P$ as an operator acting between ordinary Sobolev spaces:

$$P : H^{s+m}(\Omega) \cap \tilde{H}^m(\Omega) \to H^{s-m}(\Omega).$$

The above formulas have no longer any sense in general because $P u$ is not flat enough. In [2], we have proved formulas for the coefficients, where we remove from $P u$ some function whose Taylor expansion in 0 is the same as the Taylor expansion of $P u$ in 0.
